

ABSTRACT

The invention provides a method, system, terminal, server, and computer program product for providing or programming a call response function, preferably a voice mail function, in a communication network which includes a call response server having a storing means. The method, terminal, system, and computer program product comprise the steps of preparing or providing, in the terminal, a programming media message, such as an MMS message, which includes response content, preferably audio content. This programming media message is transmitted from the terminal to the call response server which stores the response content of the media message. When a call or session request of another terminal directed to the terminal is forwarded to the call response server the response content is played or transmitted to the another terminal.
